What is Clustering

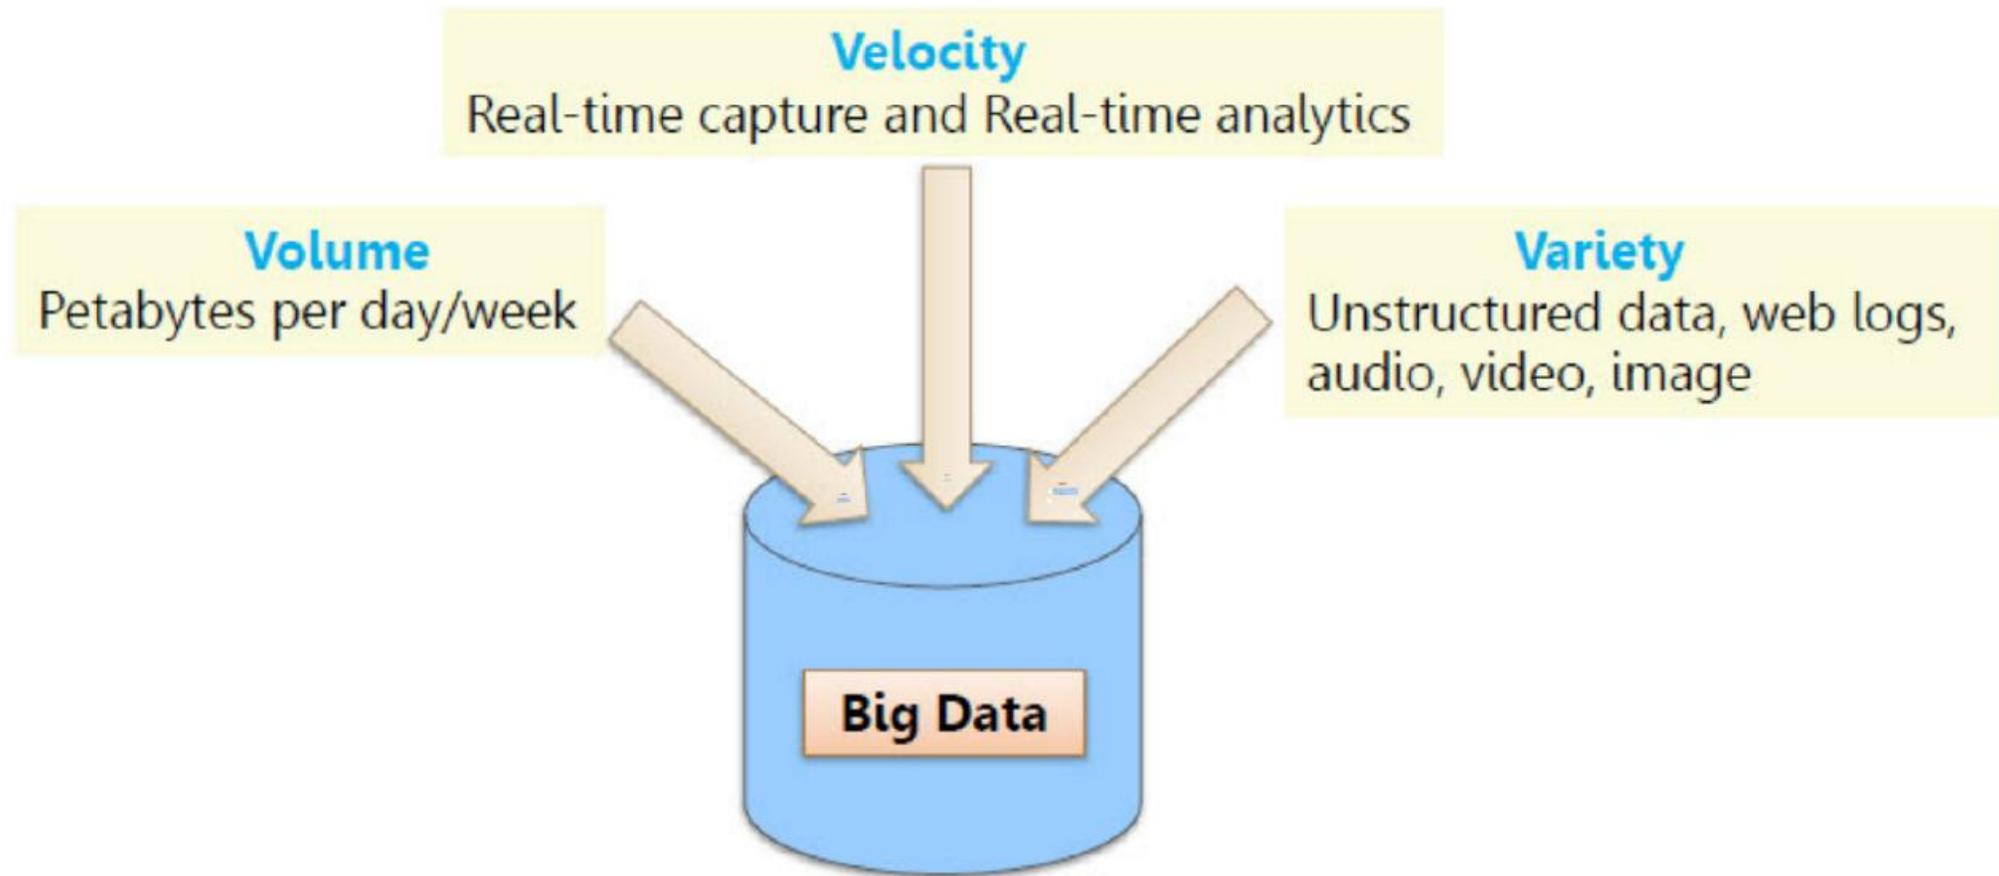

Is a method in which, data are divided into groups in a way that objects in each group share more similarity than with other objects in other groups

Volume

Refers to large amount of data. Criteria:

- size of data
- Handling high dimensionality
- Handling outliers / noisy data

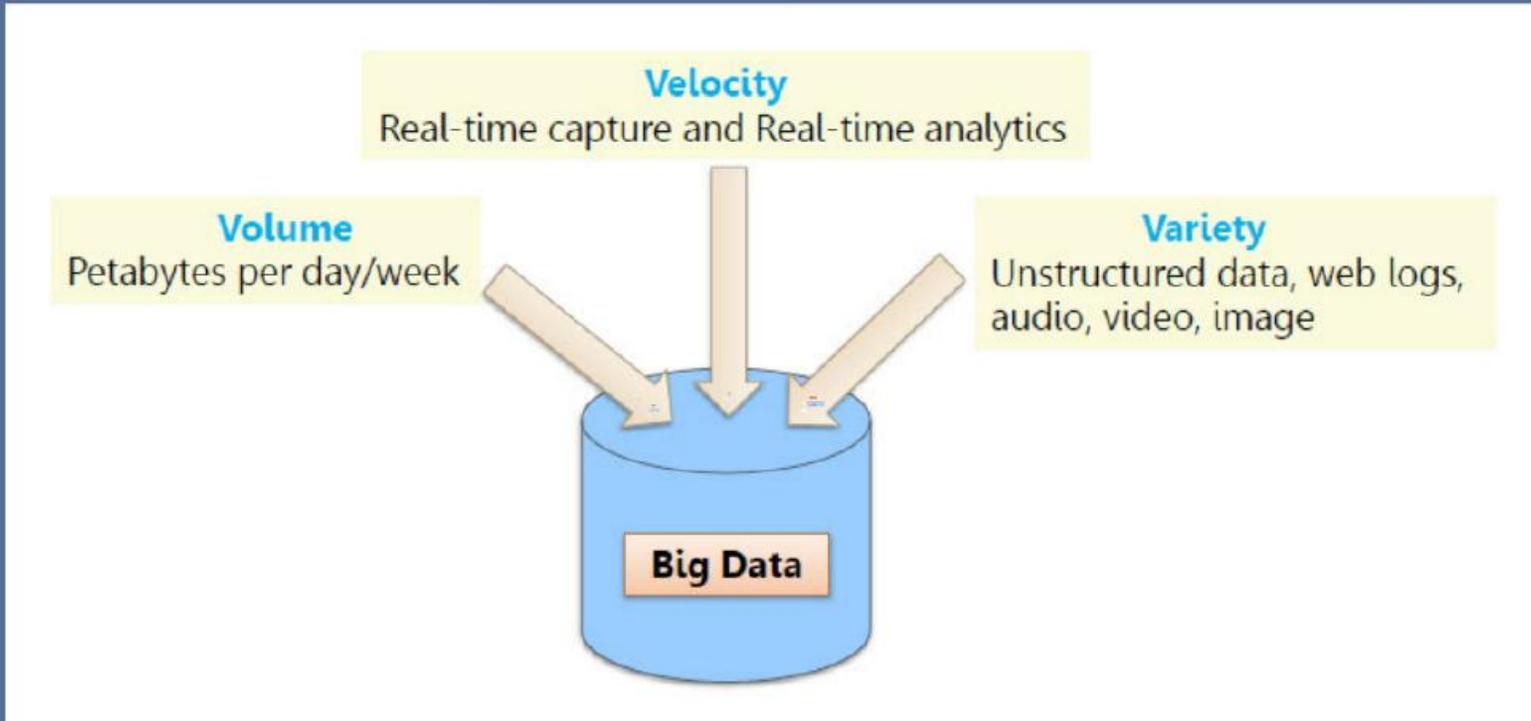

Velocity

Refers speed of processing data. Criteria:

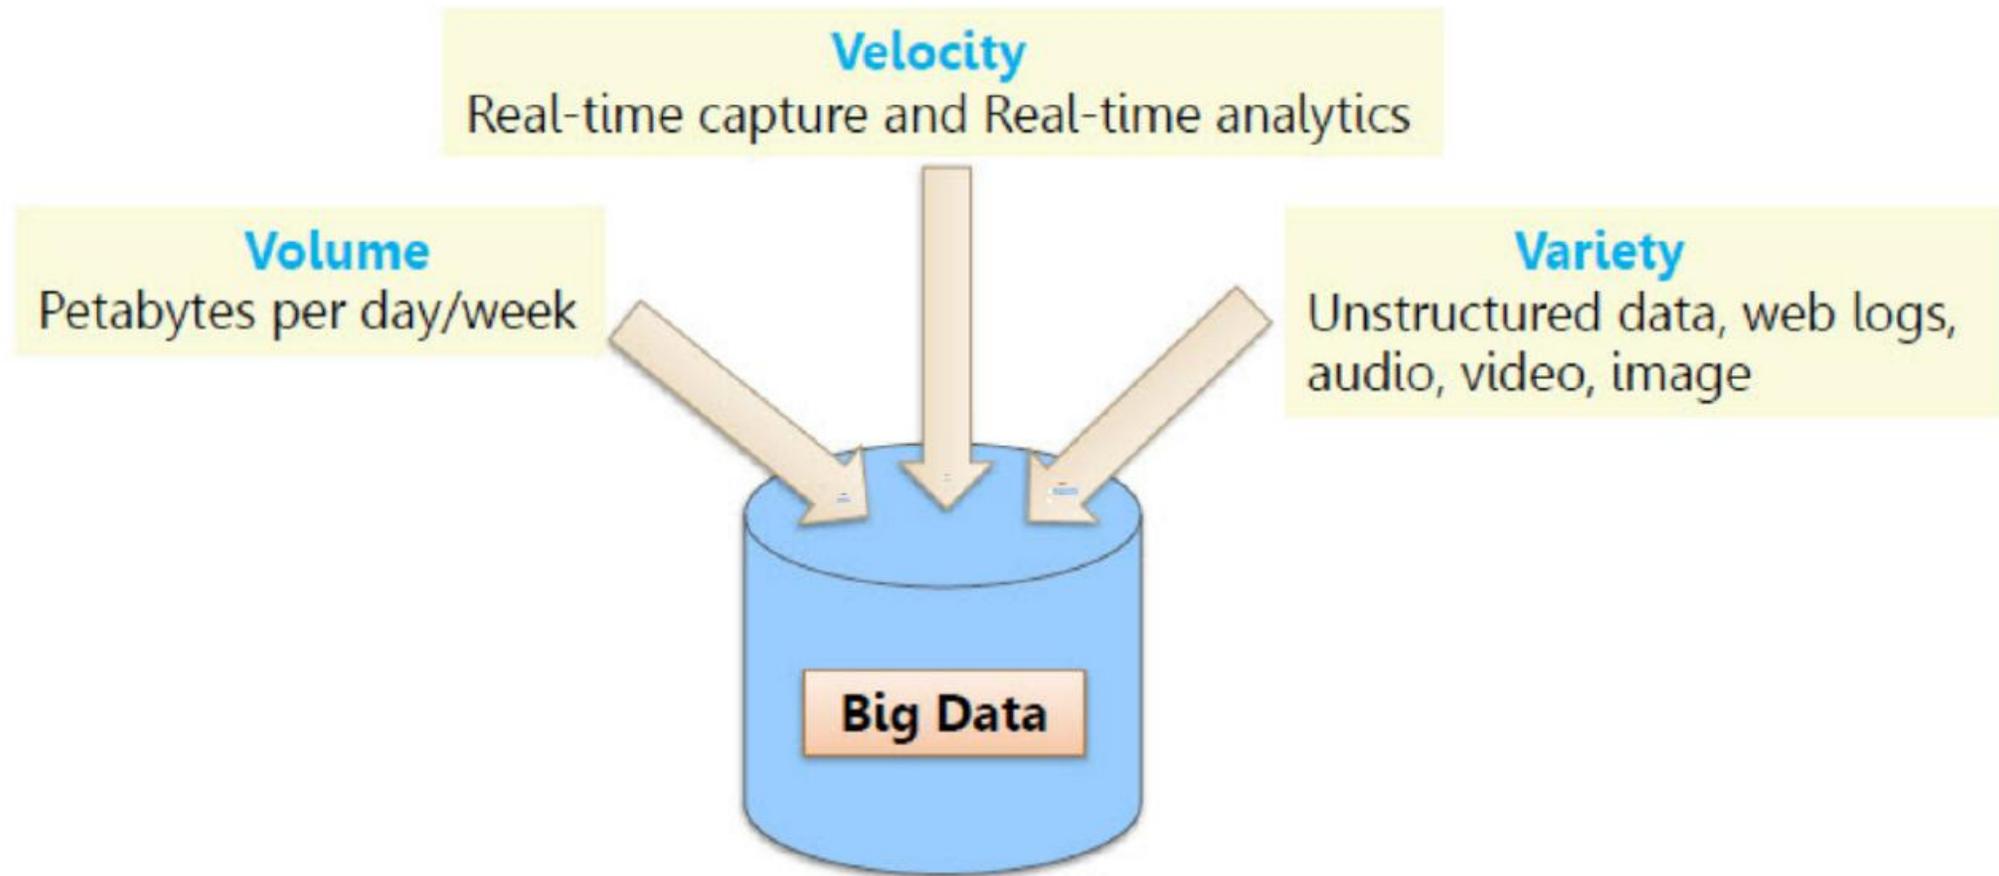

- Complexity of algorithm
- The run time performances

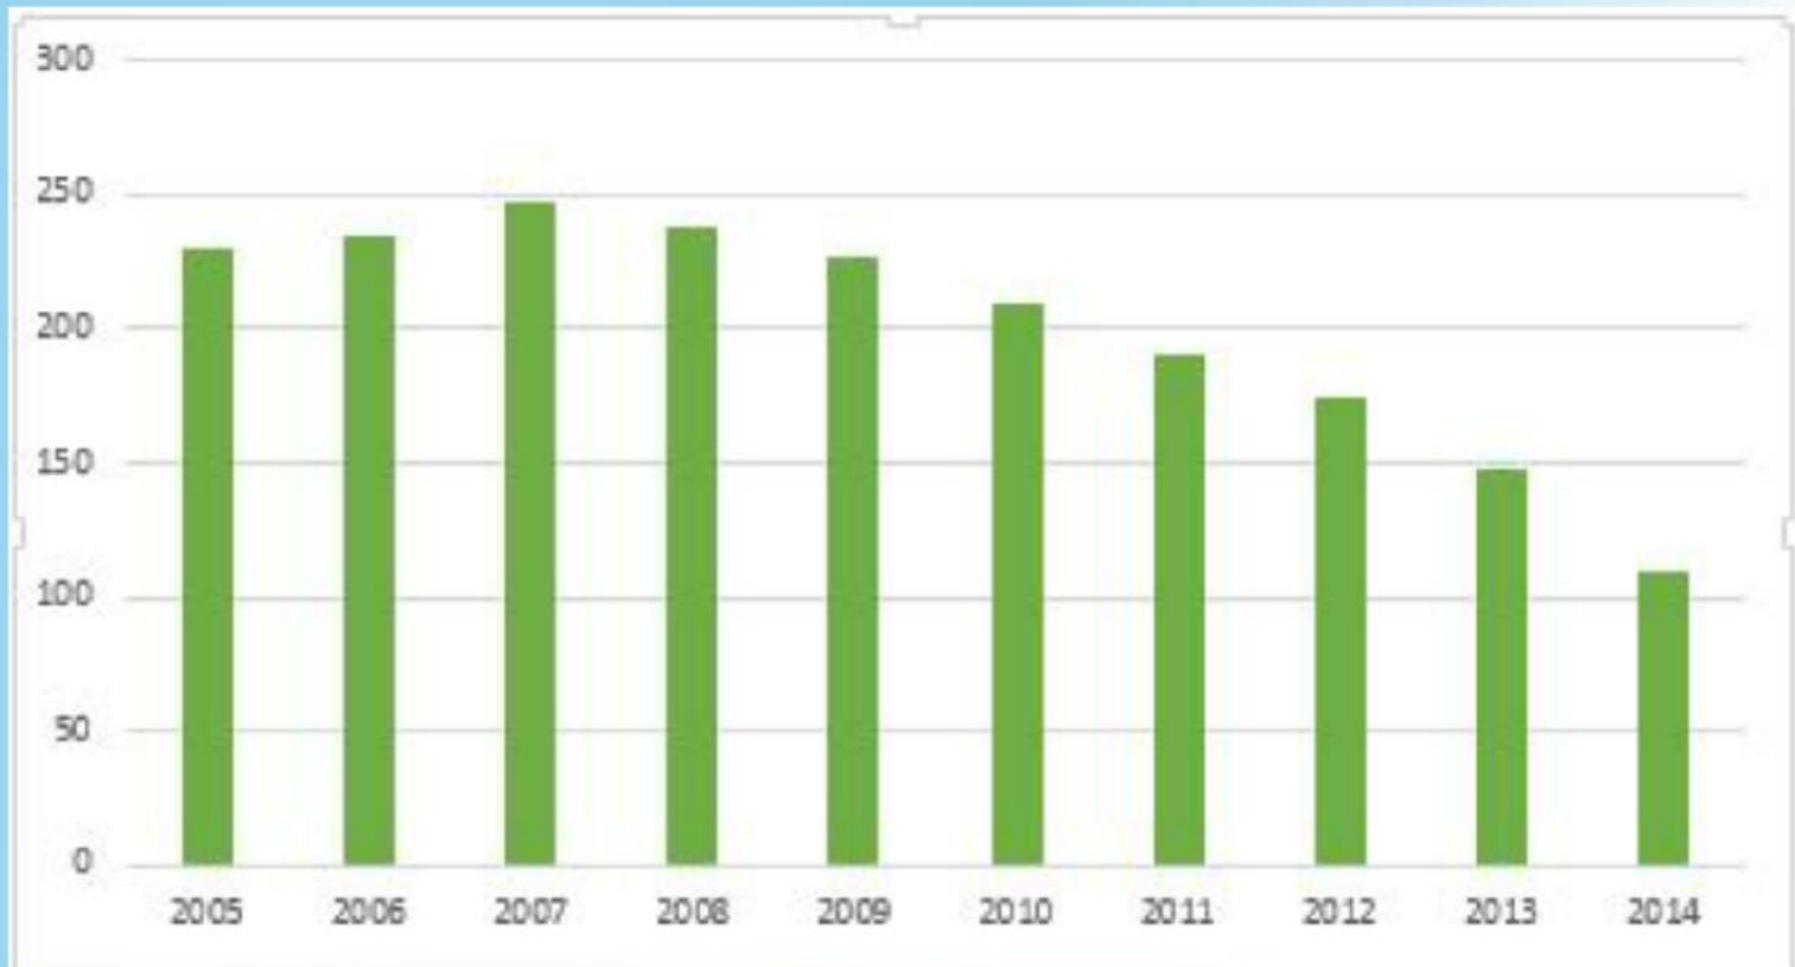

Variety

- Refers to the ability to handle different type of data. Criteria:
 - Type of data
 - Clusters shape

Big Data Clustering Algorithms

Partitioning

Hierarchical

Density-based

Parallel and Distributed

- BDC
- Density Based Distributed Clustering
- Parallel k-means

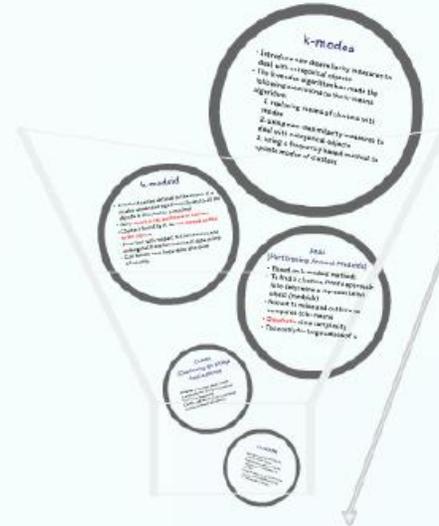

Big Data Clustering Algorithms

clustering algorithms according to different categorization schemes

**clustering algorithms according to different
categorization schemes**

Partitioning

- Partitioning algorithms use the distances between the objects directly in order to optimize a global cluster criteria
 - Construct a (flat) (single level) partition of a database D of n objects into a set of k clusters
 - The k-means algorithm is best suited for large data set because of its efficiency in clustering large data sets
- K-means Problem:**
- Can't determine the number of cluster
 - Handle dataset with only **numerical attributes**
 - Can't handle noise
 - Its performance depends strongly on the initial centroids and may get trapped in local optimal solutions

- Partitioning algorithms use the distances between the objects directly in order to optimize a global cluster criterion
- Construct a flat (single level) partition of a database D of n objects into a set of k clusters
- The k -means algorithm is best suited for large data set because of its efficiency in clustering large data sets

K-means Problem:

- Can't determine the number of cluster
- Handle dataset with only **numerical attributes**
- Can't handle noise
- Its performance depends strongly on the initial centroids and may get trapped in local optimal

k-modes

- Introduce new dissimilarity measures to deal with categorical objects
- The k-modes algorithm has made the following extensions to the k-means algorithm:
 1. replacing means of clusters with modes
 2. using new dissimilarity measures to deal with categorical objects
 3. using a frequency based method to update modes of clusters

k-medoid

- A medoid can be defined as the object of a cluster whose average dissimilarity to all the objects in the cluster is minimal
- Very **robust to the existence of outliers**
- Clusters found by it **do not depend on the order objects**
- Invariant with respect to translations and orthogonal transformations of data points
- Can handle very large data sets quite efficiently

PAM

(Partitioning Around Medoids)

- Based on k-medoid methods
- To find k clusters, PAM's approach is to determine a representative object (medoids)
- Robust to noise and outliers as compared to k-means
- **Quadratic** time complexity
- Too costly for large values of n

CLARA (Clustering for Large Applications)

Markus & Doran note that it is more computationally efficient than PAM for large data sets. CLARA applies the PAM algorithm to a subset of the data.

CLARANS

Using sampling technique to select medoids. CLARANS is a stochastic algorithm. It is a heuristic method to find a good medoid.

k-modes

- Introduce new dissimilarity measures to deal with categorical objects
- The k-modes algorithm has made the following extensions to the k-means algorithm:
 1. replacing means of clusters with modes
 2. using new dissimilarity measures to deal with categorical objects
 3. using a frequency based method to update modes of clusters

k-medoid

- A medoid can be defined as the object of a cluster whose average dissimilarity to all the objects in the cluster is minimal
- Very **robust to the existence of outliers**
- Clusters found by it do **not depend on the order objects**
- Invariant with respect to translations and orthogonal transformations of data points
- Can handle very large data sets quite efficiently

PAM

(Partitioning Around Medoids)

- Based on k-medoid methods
- To find k clusters, PAM's approach is to determine a representative object (medoids)
- Robust to noise and outliers as compared to k-means
- **Quadratic** time complexity
- Too costly for large values of n

CLARA

(Clustering for LARge Applications)

PAM has a drawback that it works inefficiently for a large data set due to its time complexity

CLARA, applies the PAM to sampled objects instead of all objects

CLARANS

- Using sampling technique to reduce search space
- Proposed in order to improve efficiency in comparison to CLARA
- In each iteration, it checks only a sample of the neighbors of the current node in the graph

Name	Inputs			Output		Complexity
	Size of Input	Handling Input Dimensionality	Handling Input Type	Output Format	Output Shape	
K-Means	Large	No	No	Numerical	Numerical	O(N)
K-Means++	Large	Yes	No	Categorical	Numerical	O(N)
t-SNE	Small	Yes	Yes	Categorical	Numerical	O(N)
FAM	Small	No	No	Numerical	Numerical	O(N ²)
CIANA	Large	No	No	Numerical	Numerical	O(N ² -log(N))
CLAUSE	Large	No	No	Numerical	Numerical	O(N)

No. Cl.	Technique	Technique	Type of Input Data	Time taken (Sec)	Output Quality	Methods	Observs.
1	K-Means++	Adaptive Clustering of K-Means++	Numerical, Categorical, Hierarchical	100 Sec	High	Clustering, Distance Matrix	Robust to outliers, handles categorical data, potential for parallelization
2	Clustering	Clustering	Numerical, Categorical, Hierarchical	100 Sec	Medium	Clustering, Distance Matrix	Simple, but may struggle with complex data distributions
3	t-SNE	t-SNE	Numerical	100 Sec	High	Clustering, Distance Matrix	Excellent for visualizing high-dimensional data, but computationally expensive
4	FAM	FAM	Numerical	100 Sec	Medium	Clustering, Distance Matrix	Simple, but may struggle with complex data distributions
5	CIANA	CIANA	Numerical	100 Sec	High	Clustering, Distance Matrix	Robust to outliers, handles categorical data, potential for parallelization
6	CLAUSE	CLAUSE	Numerical	100 Sec	High	Clustering, Distance Matrix	Robust to outliers, handles categorical data, potential for parallelization

Name	Valume			Variety		Velocity
	Size of Dataset	Handling High Dimensionality	Handling Noisy Data	Type of Dataset	Clusters Shape	complexity of Algorithm
K-Means	Large	No	No	Numerical	Non-convex	$O(nkd)$
K-modes	Large	Yes	No	Categorical	Non-convex	$O(n)$
K-medoids	Small	Yes	Yes	Categorical	Non-convex	$O(nk)$
PAM	Small	No	No	Numerical	Non-convex	$O(k(n-k)^2)$
CLARA	Large	No	No	Numerical	Non-convex	$O(k(40+k)^2+k(n-k))$
CLARANS	Large	No	No	Numerical	Non-convex	$O(kn^2)$

Sr. No.	Technique	Technique	Type of Dataset Used	Execution Time	Cluster Quality	Merits	Demerits
1	ELM Kmeans and ELM NMF	Solve the clustering problem by using ELM feature on K-means and Fuzzy C-means.	Datasets from UCI Machine Learning Repository and Document Corpus.	Very Good	High	ELM features are easy to implement and ELM Kmeans produce better results than Mercer kernel based methods.	Number of clusters should be more than 300 else performance is not optimal.
3	Clustering based on Cuckoo Search Optimization	It is a metaheuristic approach which avoids problem of k-means.	Four UCI Machine Learning Repository Datasets	Very Good	Moderate	It is easy to implement and has good computational efficiency. It also improves method to detect best values.	Quality of clusters obtained is high.
4	K-MCI	A hybrid approach to overcome local optima problem. K-means is modified with cohort intelligence.	Six standard datasets from UCI Machine Learning Repository	Good	Moderate	Convergence speed is better than heuristic algorithms and it is efficient and reliable.	Number of clusters should be prior.
5	Parallel Annealing Particle Clustering Algorithm	It resolves issue of large-scale computation problem by paralleling particle swarm optimization.	Large Test Datasets	Very Good	Moderate	Computation time is reduced and clustering quality is also improved.	Does not find the best global optimization solution.
6	PFClust	To find optimal clusters automatically without using prior knowledge of cluster.	Synthetic Datasets	Very Good	Low	It does not require any prior knowledge to find optimal clusters. It can be parallelized and executes largest dataset in minutes.	It does not require an prior knowledge to find optimal clusters. It can be parallelized and executes largest dataset in minutes.

Hierarchical

Hierarchical algorithms decompose the data base into several levels of nested partitionings and iteratively splits D into smaller subsets until each subset consists of only one object. In such a hierarchy, each node of the tree represents a cluster of D .

BIRCH

Proposed by: Angueiro
Year: 1998
Complexity: $O(n \log n)$
Input: A set of data points
Output: A set of clusters
Algorithm: Iterative splitting of data points into clusters based on a distance metric. The algorithm starts with a single cluster and iteratively splits it into smaller clusters until a stopping criterion is met. The stopping criterion is based on the number of clusters and the maximum number of points per cluster.

Algorithm	Complexity	Input	Output	Year
BIRCH	$O(n \log n)$	A set of data points	A set of clusters	1998
DBSCAN	$O(n^2)$	A set of data points	A set of clusters	1996
K-Means	$O(nk)$	A set of data points and a number of clusters k	A set of clusters	1955
Agglomerative Clustering	$O(n^3)$	A set of data points	A set of clusters	1960s
EM	$O(nk)$	A set of data points and a number of clusters k	A set of clusters	1970s

Hierarchical algorithms decompose the data base into several levels of nested partitionings and iteratively splits D into smaller subsets until each subset consists of only one object. In such a hierarchy, each node of the tree represents a cluster of D .

BIRCH

Properties of algorithm

- Handles mixed types of attributes
- Automatically determine the best number of clusters (A desirable feature in clustering is to determine the number of clusters automatically)
- Identifies outlier or noise data records (95%)
- Linear scalability by increasing data set (We test the scalability of our algorithm by increasing number of data records and number of attributes.)
- Generates better quality clusters than the traditional k-means algorithms

Sr. No.	Technique	Technique	Type of Dataset Used	Execution Time	Cluster Quality	Merits	Demerits
1	ACA-DTRS and FACADTRS	Extension of DTRS to find number of clusters automatically.	Synthetic and Real World datasets	Very Good	High	It detects accurate number of cluster without human interference without losing function quality. Also speedup execution time.	Its limitation is that it cannot work for boundary region.
2	SOHAC	It deals with the size of tick data which is growing in size rapidly.	Three real world datasets by investment bank.	Very Good	Low	Queries can efficiently run. Clusters can be found in significant running time.	This algorithm is proposed for tick data only.
3	HGCUDF	Reduces scope of search and minimized data space by divide and conquer for hierarchical grids.	Vast Computerised Datasets.	Very Good	Moderate	It can be applied on parallel platform and speed of spatial data mining is increased.	NA.
4	SWIFT	Model based clustering method to deal with large high dimensional data sets via modern flow cytometry.	Large FC Datasets and Synthetic Datasets	Good	High	It is task typical and has capability to detect rare population in large datasets.	Limited to only a particular task for clustering.
5	BIRCH	It is offer a solution to data base that its size larger than the memory size.	Multiple datasizes			It can handle noise effectively and find a good clustering with a single scan of the dataset and improve the quality with a few additional scans	It is well when clusters are not spherical It is order sensitive

Density-based

Clusters are regarded as regions in which the objects are dense, and which are separated by regions of low object density

Cluster	Centroid	Size	Distance	Label	Members
1	(1.5, 1.5)	10	0.5	High	(1.2, 1.2), (1.3, 1.3), (1.4, 1.4), (1.5, 1.5), (1.6, 1.6), (1.7, 1.7), (1.8, 1.8), (1.9, 1.9), (2.0, 2.0), (2.1, 2.1)

Density-based

Clusters are regarded as regions in which the objects are dense, and which are separated by regions of low object density

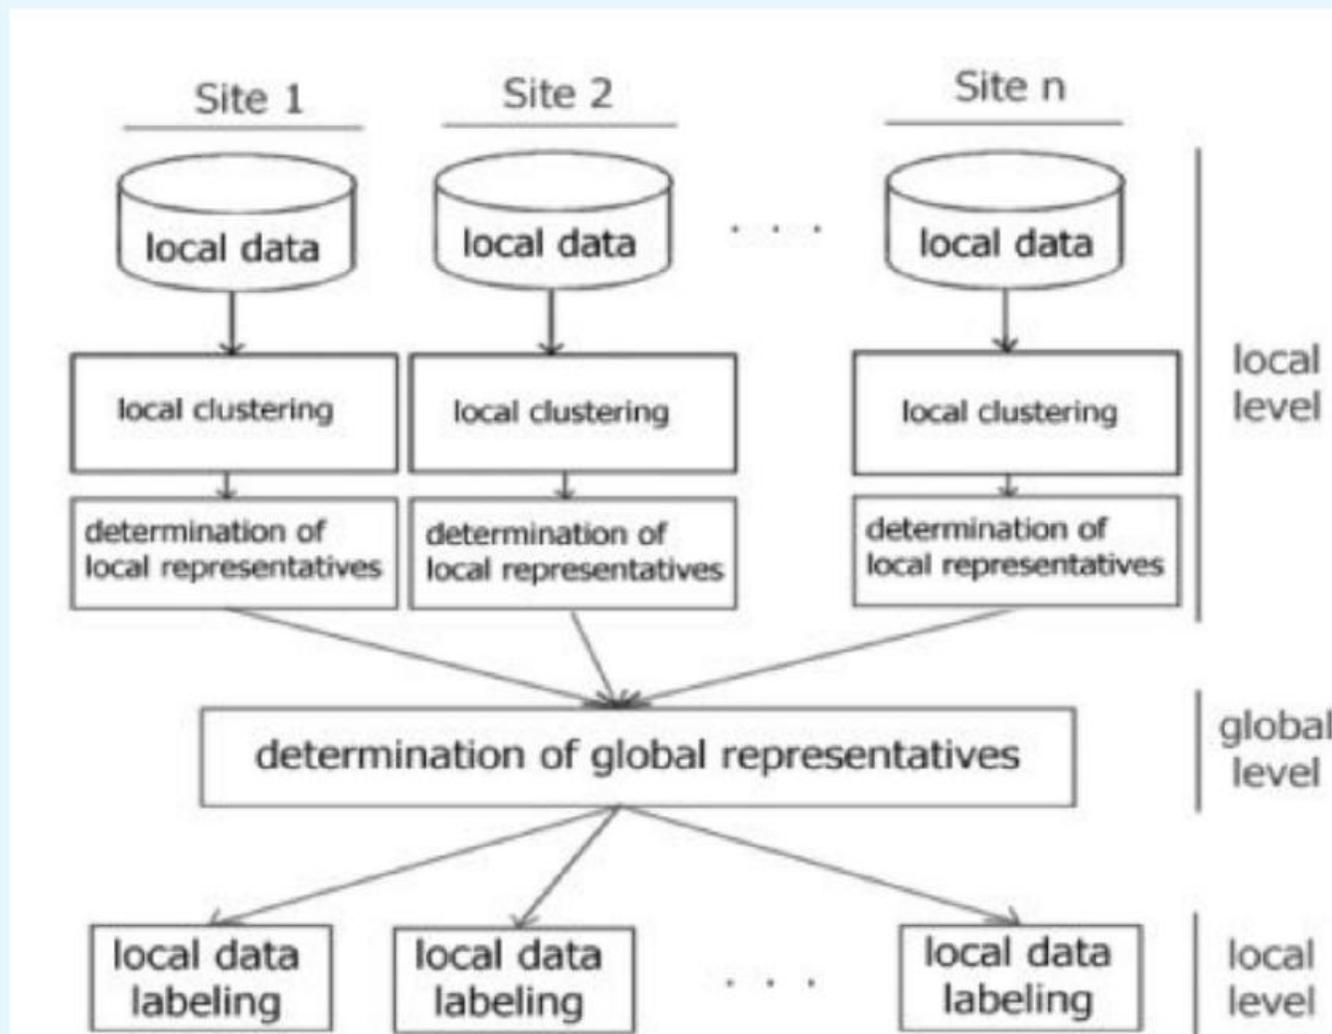

Sl. No.	Technique	Technique	Type of Dataset Used	Execution Time	Cluster Quality	Merits	Demerits
1	DMMStream	It resolves the issue of real-time data streaming. It uses concept of mini-micro clusters.	Real and Synthetic Datasets	Very Good	High	Determine correct number of cluster with increase quality while maintaining complexity time. Filter noise from data.	With macro-scale clustering it is little complex to implement this technique on all real world datasets.
2	DBCUREMR	It deals with issue of clustering big data problems. It finds clusters with varying densities and is parallelized with MapReduce.	Synthetic data and Real life data.	Very Good	High	It is easy to parallelize. Cluster with varying densities are found accurately. It not sensitive to cluster with varying densities.	It takes much computation time
3	Clustering based on Cuckoo Search Optimization	It is a metaheuristic approach which avoids problem of	Four UCI Machine Learning Repository Datasets	Very Good	Moderate	It is easy to implement and has good computational efficiency. It also improves method	Quality of clusters obtain is not very high.

		k-means.				to detect best values.	
4	DBDC	It is a parallel version of its serial interpretation to improvement in scaling and speed of algorithm				It's 30 times faster than its serial interpretation	Complexity of imlementation
5	G-DBSCAN	Use of power of GPU instead of CPU to speed up the computation				It is a accelerated parallel algorithm for density-based clustering algorithm It's 112 times faster than its serial version	Complexity of imlementation

Parallel and Distributed

• DBDC

- DBDC
Density Based Distributed Clustering
- Parallel k-means

- **DBDC**
Density Based Distributed Clustering
- **Parallel k-means**

Open Issues

- Deploy clustering algorithms on GPU based MapReduce frameworks to achieve better scalability and speed
- Improvement k-means

Conclusion

- In this study the improvement trend of data clustering algorithm were discusse, the future of clustering is tied with distributed computing. Although parallel clustering is very useful for clustering, MapReduce framework provides a very satisfying base for implementing clustering algorithms.
